Bayesian Model for March Madness Score Differential Prediction

Eftyghia Kourtelidis

2026-04-04

Bayesian Linear Regression

This notebook predicts tournament point differential using a Bayesian linear regression model fit with brms. The model uses pairwise difference features between Team 1 and Team 2 derived from regular season statistics, with team-level random effects to account for residual team-specific variability.

Features

For each statistic, features are computed as Team 1 minus Team 2, so each row is a vector encoding relative strength between the two teams for that matchup:

- SeedDiff: difference in tournament seed number
- WinPctDiff: difference in regular season win percentage
- ScoreDiffDiff: difference in average regular season point differential
- OffDiff: difference in average points scored (offensive strength)
- DefDiff: difference in average points allowed (defensive strength)
- SeedDiff:WinPctDiff: interaction between seed and win percentage differences

Preprocessing

- Train/test split by chronological year (2008–2022 train, 2023–2025 test) to match the time series split.
- Team assignments (Team 1 vs. Team 2) are randomized to remove any systematic bias from winners always appearing on one side in the raw data.
- All features are standardized using training data only, then the same transform is applied to test years.

Model

A Bayesian linear regression model with Gaussian likelihood:

$$y_i \mid w, \sigma, x_i \sim \mathcal{N}(\mu_i = w^T x_i + u_{T1} + u_{T2}, \sigma^2)$$

where u_{T1}, u_{T2} are team-level random intercepts that account for residual team-specific variability not captured by the observed features.

Priors

$$w_j \sim \mathcal{N}(0,1), \quad \alpha \sim \mathcal{N}(0,5), \quad \sigma \sim \text{Exponential}(1), \quad u_j \sim \mathcal{N}(0,\tau^2)$$
